Abstract: *According to this matter that the connection of diverse metals such as AL 5A06 with 660° melting point and steel SU 321 with 1385° melting point with different thermal features like the expansion coefficient and conductivity for the connection in the fusion welding conditions causes the creation of internal pressure after the welding. Then, the connection of these two kinds of metal, despite its necessity and specific application by the fusing method, would be resulted in considerable breakdown and impairments; so, the method of soldering (arc welding) was applied with inert Argon-based shielding and with Pulse TIG machine with developed technology and application of cover of plating Zn on SU 321 and producing the galvanized steel on the steel SU 321 and for the reason of increase of the speed of soldering operations with being lower of the current intensity, the formation of the tiny fines at lower surfaces of the weld pool would be faced with difficulty. So, for the increase of formation of tiny fines instead of coarse fines, the progressive increase of current strength according to the increase of soldering speed is one of the factors of formation of the tiny fines. So, it can be said that the current intensity is a factor effective on providing the condition for creating the TIG soldering speed in the connection of AL 5A06 and SU 321.*
Taxonomy:
Galvanization: cover of aluminum on steel, AL 5A06: aluminum alloy
Progressive increase: staircase increase, SU 321: stainless steel, Pulse: pulsed.

Keywords: *Increase of Current, Possibility of TIG Soldering, Speed in Aluminum*

INTRODUCTION

The necessity of the connection of similar and diverse metals to each other has been of observable subjects of today and has special status among the industries; and always many efforts have been made to achieve the technology of metals connection (A. S. M, 1976). Among different kinds of connections, the special attention has been paid to the weld connections because of their resistance and the product of these efforts is the variety of welding. Among different welding methods with developed technology, special attention has been paid to the connection of diverse metals by welding in the industries specially the industries of aerospace and projectile, and the industries of topography in making the very exact digital cameras and the exhaust manifold and connecting the cylinder- head to the leg of injectors and dynamo and dashboard; and for this purpose, it was decided to weld the diverse metal of aluminum to the galvanized steel because of different reasons such as different melt temperature and expansion coefficient and high wettability at melt temperature of AL in soldering operations by the welding Pulse TIG machines(A.Althouse et al., 1984; H. W.

Pollack, 1988). With regard to the literature review of research, many studies was done in 2009 by the researchers of this industry like J.L.S, C.B.L, C.L.F, S.B.A, J.L, G.C, and L.Y; and these studies were carried out in regard of the connection of two diverse metals Aluminum Alloy and galvanized Steel by the use of Pulse TIG machines with different features such as " connection of two diverse metals in different conditions", "suitable wettability of galvanized matter", "expansion of cable of welding the liquid aluminum on the surfaces of steel", " increase of efficiency and application of inert Argon in this soldering and protection of proper mechanical features of the matters in different conditions of speed of welding operations" ; that in this welding, the most important parameters such as the increase of gas flow rate are considerable(Moeinian 1st volume, 2006; Moeinian 3rd volume, 2006; Moeinian second volume, 2006). The gas flow rate is one of the most effective factors in the protection of connection quality at high speed and because, in literature review of the research, this kind of connection has been studied in the operations with high speed; so, this parameter was studied in this research due to its effect on the speed of operations of diverse metals connection (V. Muthupandi et al., 2003).

Procedure

In the connection of these two diverse metals, a segment of stainless steel SU 321with dimensions of 120mm×50mm×3mm and slat angle of 45º and melting point of 1385º and a segment of Aluminum Alloy with dimensions of 120mm×50mm×3mm in the slat angle of 30º and melting point of 660º and a filler of Al Si 4047 with different diameters of 2mm and 3mm were selected and after plating the stainless steel by the use of Zn and its galvanization for the purpose of assimilating the melting point of steel with the one of Aluminum alloy and providing the condition for the connection and (copper- fastener with dimensions of 130mm×110×10mm and with slope angle of 120mm×8mm×0.5mm for controlling the segments temperature) and with a fixture equipped with two plate fixatives and the tractor including the torch equipped with the speed control systems; and the safety equipment such as crash helmet, gloves, shoes, and specific clothes were prepared. Then, the welding operation was done by the use of inert argon gas with a nozzle with different diameters for the protection of quality of soldering and the Pulse TIG AC- DC – Model 200 Pars welding machine with different speeds were provided for evaluating the possibility of soldering operations with further speed and efficiency; and after machining the welded segments, for doing the tensile and microhardness test operations, the Imstron4208 tensile and Bohler micromet11 microhardness testers were applied respectively for testing the tensile and microhardness of the welded segments (W. F. Hosford & R. M. Caddell, 1983; , Zandi, Y, 2008).

Discussion and conclusion

Because the amount of Zn in the segment of Al 5A06 was 0.030% and in the filler of Al Si 4047 was <0.05; but it did not exist in SU 321 segment and for this reason, the melting point of steel is more than the one of AL and their connection is possible only by depressing the melting point of steel by its galvanization. So, by plating Zn on the steel, it was galvanized and by assimilating the melting point of two segments and the use of inert argon gas for the protection of welding quality, the AL 5A05 and SU 321 were connected by the use of welding machine that was most suitable for this connection (Pulse TIG). To access to the further efficiency and output rate, the speed of welding operations was changed from 80mm/s to 165mm/s. That this affair is for the reason of reduction of the heat entered into the lower surfaces of weld pool and also the reduction of fines and the tensile resistance of the connection. For solving this problem, the proper increasing current intensity was applied that was an effective factor in the input heat and also the formation of tiny fines in the weld pool
